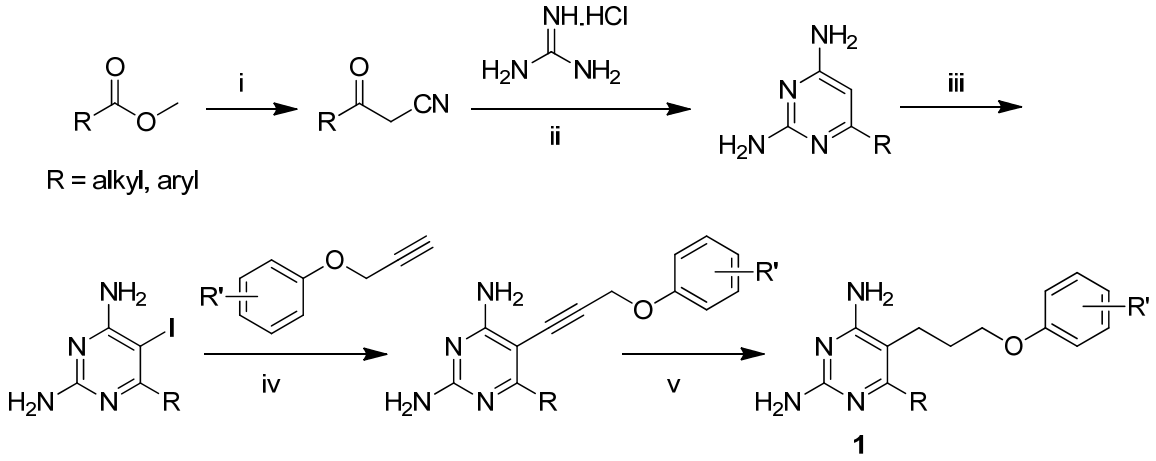
Antifolates are a class of therapeutic agents that have potential application for cancer chemotherapy and for the treatment of parasitic and bacterial infections.[1] In Africa, the parasite that causes malaria, *P. falciparum*, is responsible for 93% of malaria deaths worldwide.[2] Substituted 2,4-diaminopyrimidines act as antifolates by targeting the enzyme dihydrofolate reductase (DHFR).[1]

We have previously prepared a series of dihydrotriazines that displayed potent activity against *P. falciparum* DHFR (*Pf*DHFR).[3] Herein we report our progress on the synthesis of a series of related substituted pyrimidines **1** in a five step process (Scheme 1) from commercially available alkyl and aryl esters.



**Scheme 1:** i) MeCN, *t*BuOK, IPA, 2-MeTHF; ii) *t*BuOK, 2-MeTHF, 100W, 100°C; iii) $HIO_3$, $H_2SO_4/H_2O$; iv) $Pd(PPh_3)Cl_2$, CuI, DIPEA, DMF; v) $H_2$, Pd/C, EtOH
